Spoiler for the rest of this talk

- **LLVM code representation is quite unique:**
 - ✧ IR is not “lowered” through the compiler
 - ✧ Truly source-language/target independent
- **LLVM supports very high-level opt/analysis:**
 - ✧ Analysis and restructuring of code
 - ✧ Supports most classical optimizations as well
- **LLVM supports very low-level work as well:**
 - ✧ Novel microprocessor/micro-architectural designs
 - ✧ Requires high-level info and low-level representation

Talk Outline

- **Lifelong Program Analysis & Optimization**
 - ✦ LLVM Virtual Instruction Set
 - ✦ LLVM Compiler Architecture
- **LLVM as a Compiler Infrastructure**
- **Recursive DS Analysis / Transformations**
- **Virtual Instruction Set Computing**
- **Summary**

Life-Long Program Optimization:

■ Multiple-stages of analysis & transformation:

- ❖ compile-time, link-time, install-time, run-time, idle-time
- ❖ Use aggressive interprocedural optimizations
- ❖ Gather and exploit end-user profile information
- ❖ Tune the application to the user's hardware

■ But what constraints do we have to meet?

- ❖ Can't interfere with the build process!
- ❖ Must support multiple source-languages!
- ❖ Must integrate with legacy systems and components!

"LLVM: A Compilation Framework for Lifelong Program Analysis & Transformation"
Chris Lattner and Vikram Adve CGO'2004

Five key capabilities are needed:

1. **A persistent, rich code representation**

- Enables analysis & optimization throughout lifetime

2. **Offline native code generation**

- Must be able to generate high-quality code statically

3. **Profiling & optimization in the field**

- Adapt to the **end-user's** usage patterns

4. **Language independence**

- No runtime, object model, or exception semantics

5. **Uniform whole-program optimization**

- Allow optimization across languages and runtime

What about previous approaches?

Approach	Persistent Rich Code	Offline Codegen	End-user Profiling	Transparent runtime	Uniform whole-prog.
Source-level Compilers		✓		✓	
Source-level Link-time IPO	through link-time	✓		✓	
Machine Code Optimizers	?	✓	✓	✓	✓
High-Level Virtual Machines	✓		✓		user code only
LLVM	✓	✓	✓	✓	✓

Our approach: The LLVM System

■ Use a low-level, but typed, representation:

- ❖ Type information allows important high-level analysis
- ❖ Code representation is truly language neutral
- ❖ Allow off-line and runtime native code generation

■ Our specific contributions:

❖ Novel features for language independence:

- Typed pointer arithmetic, exception mechanisms

❖ Novel capabilities:

- First to support all 5 capabilities for lifelong optzn

Why not a HLL VM like CLI/JVM?

■ Differing goals \Rightarrow differing representations:

- ❖ HLL VMs: classes, inheritance, mem. mgmt, runtime...
- ❖ LLVM: calls, load/stores, arithmetic, addressing, etc...

■ Implications:

- ❖ *Verifiable* CLI is not truly language neutral
- ❖ Cannot optimize VM code **into** the application code
- ❖ HLL VMs require specific runtime environments
- ❖ CLI is not used directly for compiler optzn/analysis

■ LLVM **complements** high-level VMs:

- ❖ HLL VM can be implemented in terms of LLVM!

Talk Outline

Talk Outline

- **Lifelong Program Analysis & Optimization**
 - ✧ LLVM Virtual Instruction Set
 - ✧ LLVM Compiler Architecture
- **LLVM as a Compiler Infrastructure**
- **Recursive DS Analysis / Transformations**
- **Virtual Instruction Set Computing**
- **Summary**

LLVM Instruction Set Overview #1

■ Low-level and target-independent semantics

- ✧ RISC-like three address code
- ✧ Infinite virtual register set in SSA form
- ✧ Simple, low-level control flow constructs
- ✧ Load/store instructions with typed-pointers

```
loop:  
  %i.1 = phi int [ 0, %bb0 ], [ %i.2, %loop ]  
  %AIAddr = getelementptr float* %A, int %i.1  
  call void @Sum(float %AIAddr, %pair* %P)  
  %i.2 = add int %i.1, 1  
  %tmp.4 = setit int %i.1, %N  
  br bool %tmp.4, label %loop, label %outloop
```

```
for (i = 0, i < N;  
    ++i)  
  Sum(&A[i]  &P),
```

LLVM Instruction Set Overview #2

■ High-level information exposed in the code

- ▷ Explicit dataflow through SSA form
- ▷ Explicit control-flow graph (even for exceptions)
- ▷ Explicit language-independent type-information
 - Explicit typed pointer arithmetic

```
loop:  
  %i.1 = phi int [ 0, %bb0 ], [ %i.2, %loop ]  
  %AIAddr = getelementptr float@ %A, int %i.1  
  call void @Sum(float %AIAddr, %pair@ %P)  
  %i.2 = add int %i.1, 1  
  %tmp.4 = setlit int %i.1, %N  
  br bool %tmp.4, label %loop, label %outloop
```

```
for (i = 0, i < N;  
    ++i)  
    Sum(&A[i]  &P),
```

LLVM Type System Details

■ The entire type system consists of:

- ✧ Primitives: void, bool, float, ushort, opaque, ...
- ✧ Derived: pointer, array, structure, function
- ✧ No high-level types: type-system is language neutral!

■ Source language types are lowered:

- ✧ e.g. `T* → T*`
- ✧ e.g. `class T { S; int X; } → { S, int }`

■ Type system allows arbitrary casts:

- ✧ Allows expressing non-type-safe languages, like C
- ✧ Does not provide safety or verifiability

LLVM Instruction Set Overview #2

■ High-level information exposed in the code

- ✧ Explicit dataflow through SSA form
- ✧ Explicit control-flow graph (even for exceptions)
- ✧ Explicit language-independent type-information
 - Explicit typed pointer arithmetic

```
loop
  %i.1 = phi int [ 0, %bb0 ], [ %i.2, %loop ]
  %AIAddr = getelementptr float@ %A, int %i.1
  call void @Sum(float %AIAddr, %pair* %P)
  %i.2 = add int %i.1, 1
  %tmp.4 = setit int %i.1, %N
  br bool %tmp.4, label %loop, label %outloop
```

```
for (i = 0, i < N;
    ++i)
  Sum(&A[i] &P),
```

LLVM Compiler Architecture

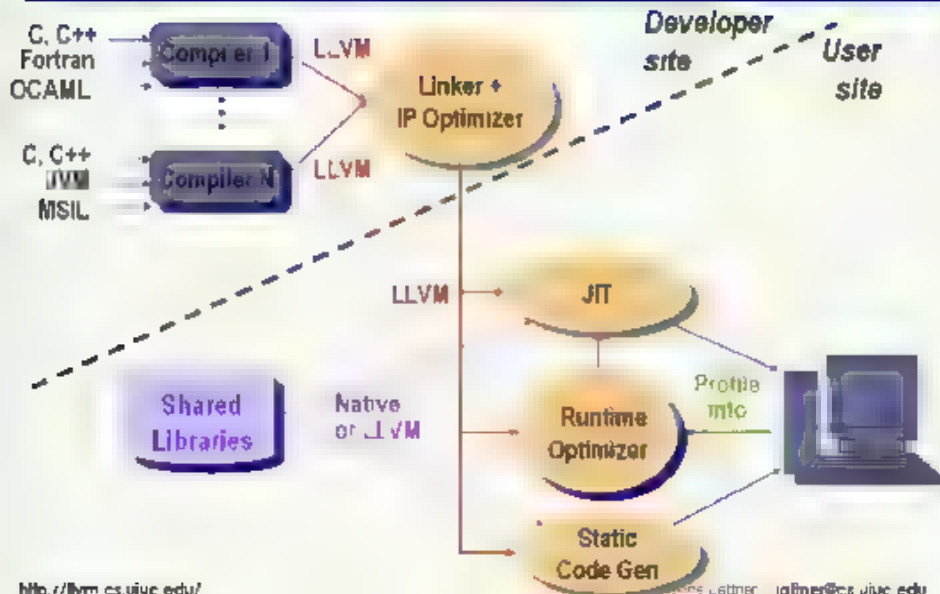

LLVM Compiler Architecture

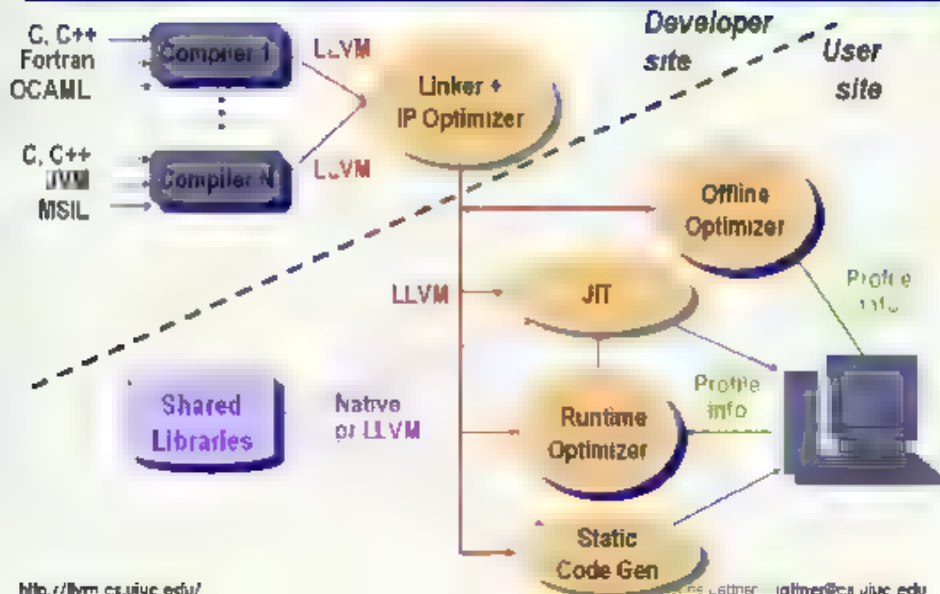

LLVM Compiler Architecture

LLVM Compiler Architecture

LLVM Compiler Architecture

LLVM provides all five capabilities:

- 1. A persistent, rich code representation:**
 - LLVM to LLVM optimizations can happen at any time
- 2. Offline native code generation:**
 - Generate high-quality machine code, retaining LLVM
- 3. Profiling & optimization in the field:**
 - Runtime and offline profile-driven optimizers
- 4. Language independence:**
 - Low-level inst set & types with transparent runtime
- 5. Uniform whole-program optimization:**
 - Optimize across source-language boundaries

Talk Outline

- Lifelong Program Analysis & Optimization
- LLVM as a Compiler Infrastructure
 - Bugpoint automated bug finder
- Recursive DS Analysis / Transformations
- Virtual Instruction Set Computing
- Summary

A Compiler Infrastructure?

- **Composable *libs* for building compiler tools:**
 - ❖ Language front-ends, static/JIT code generators, aggressive optimizations, static analysis systems, profile feedback, target information, .
- **Easy to write and debug compiler parts:**
 - ❖ Many samples, automated debugging tools, modularity
- **Encourage reuse, but don't require it:**
 - ❖ Can write a new register allocator or optimization
 - ❖ Can completely replace the code generator

Primitive LLVM Tools

- **'llvm-as', 'llvm-dis':** translate `.ll` \leftrightarrow `.bc`
- **'llvm-link':** Link two LLVM files together
- **'opt':** Run pass sequence on an LLVM file
 - Useful for unit testing, manual experimentation, etc
 - `opt -lcm -gcse x.bc -o y.bc`
- **'llc':** LLVM static code generator
 - Codegen llvm to a textfile `llc x.bc -march=x86 -o x.s`
- **'lli':** LLVM Execution Engine (JIT/Interpreter)
 - `lli ls.bc -l`

Tools used by the C/C++ compiler

- **'gccas': Compile-time optimizer:**
 - ✧ Parse ll file
 - ✧ Run a canned sequence of 41 LLVM passes
 - ✧ Output a .bc file
- **'gccld': Linker and link-time optimizer:**
 - ✧ Links bc files, libraries, handles searching a files
 - ✧ Runs 20 more LLVM passes
 - ✧ Can output .bc file, or native exe using 'lrc'
- **Tools are built by picking the appropriate components and writing glue code**

The Bugpoint automated bug finder 1

- **Simple idea: automate 'binary' search for bug**
 - ◊ Bug isolation which passes interact to produce bug
 - ◊ Test case reduction reduce input program
- **Optimizer/Codegen crashes:**
 - ◊ Throw portion of test case away, check for crash
 - If so, keep going
 - Otherwise, revert and try something else
 - ◊ Extremely effective in practice
- **Simple greedy algorithms for test reduction**
- **Completely black-box approach**

Debugging Miscompilations

■ **Optimizer miscompilation:**

- ❖ Split testcase in two, optimize one. Still broken?
- ❖ Keep shrinking the portion being optimized

■ **Codegen miscompilation:**

- ❖ Split testcase in two, compile one with CBE, broken?
- ❖ Shrink portion being compiled with non CBE codegen

■ **Code splitting granularities:**

- ❖ Take out whole functions
- ❖ Take out loop nests
- ❖ Take out individual basic blocks

The Bugpoint automated bug finder

- **Simple idea: automate 'binary' search for bug**
 - Bug isolation which passes interact to produce bug
 - Test case reduction reduce input program
- **Optimizer/Codegen crashes:**
 - Throw portion of test case away, check for crash
 - If so, keep going
 - Otherwise, revert and try something else
 - Extremely effective in practice
- **Simple greedy algorithms for test reduction**
- **Completely black-box approach**

Debugging Miscompilations

■ **Optimizer miscompilation:**

- ✧ Split testcase in two, optimize one. Still broken?
- ✧ Keep shrinking the portion being optimized

■ **Codegen miscompilation:**

- ✧ Split testcase in two, compile one with CBE, broken?
- ✧ Shrink portion being compiled with non CBE codegen

■ **Code splitting granularities:**

- ✧ Take out whole functions
- ✧ Take out loop nests
- ✧ Take out individual basic blocks

How well does this thing work?

■ Extremely effective:

- ✧ Can often reduce a 100K LOC program and 60 passes to a few basic blocks and 1 pass in 5 minutes
- ✧ Crashes are found much faster than miscompilations
 - no need to run the program to test

■ Limitations:

- ✧ Program must be deterministic
 - or modified to be so
- ✧ Finds “a” bug, not “the” bug

LLVM Compiler Status

Public releases in Oct 03 Dec 03 Mar 04

Many downloads external contributors ~200K LOC

<http://lvm.cs.uiuc.edu/>

■ Release includes:

Front ends C C++ (based on GCC parser)

Back ends C Sparc X86 (offline or online, [PPC soon])

EE System: Sparc JIT X86 JIT interpreter

Link-time IPO, many global opts, profile feedback, aggressive alias analysis ...

■ Under development:

JVM, MSIL, OCAML front-ends (plus Python Ruby Scheme)

Trace-driven runtime optimizer

• **Many other derivative projects**

Recursive Data Structures

- **RDS are widely used by many programs:**
 - Linked-lists, binary trees, graphs, heaps, ...
- **RDS perform poorly on modern architectures:**
 - RDS nodes are spread randomly in memory
 - Irregular access patterns are bad for locality
 - Small pointer chasing loops are common

Standard Approaches

- Analyses and xforms focus on primitives:
 - ▷ Disambiguate/eliminate individual loads and stores
 - ▷ Reorder, split, or merge structure definitions
 - ▷ Heuristics for co-locating heap objects
- Q: Can we target *entire data structures*?

Why haven't we done this yet?

- **Existing analyses are usually conservative:**
 - ✧ Treat all objects allocated by one malloc the same
 - ✧ Type-safe language required for field-sensitivity
 - Type-unsafe languages implies extremely expensive or unsound analyses
- **Aggressive analyses are very expensive**
 - ✧ e.g. shape analysis
 - ✧ Usually can't work without whole program
- **Runtime layout of heap objects is unknown:**
 - ✧ Limits approaches to the simple techniques earlier

The *Macroscopic* Approach

Analyze and Transform Entire Data Structures

■ **Data Structure Analysis:**

- ▷ An *aggressive & scalable* analysis **for the real world**
- ▷ Identifies data structures & their properties
- ▷ Context-sensitive field-sensitive, flow-insensitive

■ **Automatic Pool Allocation:**

- ▷ Transform program to allocate from **memory pools**
- ▷ Provides partial layout control of nodes to the compiler
- ▷ Can identify dynamic DS objects at *runtime*

■ **Many applications of the above are possible**

Talk Outline

- Lifelong Program Analysis & Optimization
- LLVM as a Compiler Infrastructure
- Recursive DS Analysis / Transformations
 - Data structure analysis
 - Automatic pool allocation
- Virtual Instruction Set Computing
- Summary

Data Structure Analysis: *Properties*

Context-sensitive, field-sensitive, yet scalable

Names heap objects by full acyclic call paths

■ 2 Compromises:

(a) unification-based (b) flow-insensitive

■ Scalable and very fast:

• $\sim O(n \log n)$: 137K lines of C code in 8 seconds

Field-sensitive only for nodes with unique type

Almost no iteration at all

■ Designed for the real world (aka harsh realities of C):

• Incomplete programs type-unsafe code

• Function pointers and recursion

✓ varargs setjmp/longjmp EH

• Does not need a call graph provided

Data Structure Analysis: What's New?

- **Fine grained tracking of incomplete information:**
 - Handle incomplete programs, partially resolved function pointers
 - Speculative field sensitivity
- **Walk SCCs of call-graph with incremental call graph**
 - Incremental* \rightarrow discover call graph during analysis
 - Walk SCCs* \rightarrow non-iterative algorithm
- **Field-sensitive *only* for type-safe memory objects**
- **(Not new) Context-sensitivity can be scalable in a unification based algorithm**

Important aspects of DSA

Field sensitivity + full context sensitivity

Identifies *instances* and *connectivity* of RDS

DSA also captures important properties of memory objects

```
int g;  
  
void twoLists() {  
    list *X = makeList(10).  
    list *Y = makeList(100).  
    addToList(X).  
    addToList(Y).  
    freeList(X).  
    freeList(Y);  
}
```

Novel Features of DSA

■ Fine-grained tracking of incomplete info:

- ✧ Memory passed into external function calls
- ✧ Speculative type-safety & field-sensitivity
- ✧ Intermediate analysis results are always correct!

■ Discovers call graph during analysis:

- ✧ No iteration or call graph approximation needed!

■ Field-sensitive for type-safe *memory objects*:

- ✧ Field-insensitive only in hopeless cases

■ DSA *safe* for *full generality* of C/C++ codes

- ✧ and efficient enough to be used!

Novel Features of DSA

- **Fine-grained tracking of incomplete info:**
 - Memory passed into external function calls
 - Speculative type-safety & field-sensitivity
 - Intermediate analysis results are always correct!
- **Discovers call graph during analysis:**
 - No iteration or call graph approximation needed!
- **Field-sensitive for type-safe *memory objects*:**
 - Field-insensitive only in hopeless cases
- **DSA *safe* for *full generality* of C/C++ codes**
 - ... and efficient enough to be used!

Novel Features of DSA

- **Fine-grained tracking of incomplete info:**
 - ◊ Memory passed into external function calls
 - ◊ Speculative type-safety & field-sensitivity
 - ◊ Intermediate analysis results are always correct!
- **Discovers call graph during analysis:**
 - ◊ No iteration or call graph approximation needed!
- **Field-sensitive for type-safe *memory objects*:**
 - ◊ Field-insensitive only in hopeless cases
- **DSA *safe* for *full generality* of C/C++ codes**
 - ◊ and efficient enough to be used!

Talk Outline

- Lifelong Program Analysis & Optimization
- LLVM as a Compiler Infrastructure
- Recursive DS Analysis / Transformations
 - Data structure analysis
 - Automatic pool allocation
- Virtual Instruction Set Computing
- Summary

Pool Allocation

■ Traditional (manual) Pool Allocation:

- ✧ Custom memory allocators
- ✧ Per-class allocators
- ✧ Often for performance reasons

■ Fully Automatic Pool Allocation:

- ✧ Each heap node in the DS Graph can become a pool
- ✧ Pools are usually type-homogenous
- ✧ Disjoint data structure instances get separate pools!

Why Segregate Data Structures?

Programs are designed around data structures

■ **Primary Goal: *Better compiler information & control***

- Compiler knows where each data structure lives in memory
- Compiler knows order of data in memory (in some cases,
- Compiler knows type information → runtime points-to graph
- Compiler knows which pools point to which other pools

■ **Incidental benefits: *Better performance***

- Smaller working sets
- Improved spatial locality
- Sometimes convert irregular to regular strides

Automatic Pool Allocation Overview

- Each DS node instance uses separate pool (for now)
- Each pool can be type-homogeneous
- Retain explicit `free()` for objects

Automatic Pool Allocation Overview

- Each DS node instance uses separate pool (for now)
- Each pool can be type-homogeneous
- Retain explicit `free()` for objects

Automatic Pool Allocation Overview

- Each DS node instance uses separate pool (for now)
- Each pool can be type-homogeneous
- Retain explicit `free()` for objects

Pool 1

Pool 2

Automatic Pool Allocation Overview

- Each DS node instance uses separate pool (for now)
- Each pool can be type-homogeneous
- Retain explicit `free()` for objects

P1 P2

P1 P2

P1 P2

Pool Allocation: Example

```
int *makeList(int Ndata,
              int *New = malloc(sizeof(int),,
              New->next = Ndata; return New;
              New->Data = Ndata; return New;
}
```

```
int twoLists(
```

```
    int *X = makeList(1,;
    int *Y = makeList(1,);
    GL = Y;
    addGToList(X);
    addGToList(Y);
    freeList(X);
    freeList(Y);
```

Pool Allocation: Example

```
int *makeList(int len)
{
    int *new = malloc(sizeof(int)*len);
    new[0] = len;
    new[1] = makeList(len-1);
    new[2] = len;
    return new;
}
```

```
int twoLists(
```

```
    list *X = makeList(1);
    list *Y = makeList(1);
    GL = X;
    addToList(X);
    addToList(Y);
    freeList(X);
    freeList(Y);
}
```

Pool Allocation: Example

```
int *makeList(int size,  
              int *data) {  
    int *new = malloc(sizeof(int) * size);  
    new->next = NULL; return new;  
}
```

```
int twoLists(int size1, int size2, int *data1, int *data2)
```

```
{  
    list *X = makeList(size1, data1);  
    list *Y = makeList(size2, data2);  
    GL = Y;  
    addToList(X);  
    addToList(Y);  
    freeList(X);  
    freeList(Y);  
}
```

Pool Allocation: Example

```
int *makeList(int n) {
    int *New = (int *) malloc(sizeof(int) * n);
    New->next = NULL;
    New->Data = 0;
    for (i = 0; i < n; i++) {
        New[i] = i;
    }
}
```

```
int twoLists(int n, int m) {
```

```
    int *X = makeList(n);
    int *Y = makeList(m);
```

```
    GL = Y;
    addGToList(X);
    addGToList(Y);
    freeList(X);
    freeList(Y);
```

Pool Allocation: Example

```

1141: list *makeList(int n) {
1142:     list *new = (list *) malloc(sizeof(list));
1143:     new->next = NULL;
1144:     new->data = newdata;
1145:     return new;
1146: }

```

Pool Allocation: Example

```
list *makeList(int n)
{
    list *New = (list *) malloc(sizeof(list));
    New->next = NULL;
    New->data = malloc(sizeof(int));
    return New;
}
```

```
int twoLists(int n, int m)
```

```

{
    list *p = makeList(n);
    list *q = makeList(m);
    GL = Y;
    addGToList(p);
    addGToList(q);
    freeList(p);
    freeList(q);
}
```

High-level pool allocation algorithm

1. Use DSA to identify data structures on the heap
 - Identifies distinct instances and type information
2. Determine lifetime of data structures
 - Escape analysis for entire data structures
3. Create pools, add pool arguments to functions
 - Interprocedural code restructuring
4. Rewrite function bodies to call poolalloc/poolfree instead of malloc/free

What about global variables?

■ The problem:

- ✧ Function accesses a node reachable from a global
- ✧ Node escapes all functions except main
 - ⇒ Must pass pool descriptor all the way from main()

■ Solution:

- ✧ Make pool descriptor a global variable itself
- ✧ Initialize it in main, access it directly where needed
- ✧ **Greatly** reduces # pool args in some programs

Two more optimizations

■ Intelligent placement of poolinit/poolfree:

- ✧ Init as late as possible, destroy as early as possible
- ✧ Standard dataflow analysis
- ✧ Can be extended interprocedurally [Aiken et al., PLDI 96]

■ Elide poolfree calls:

- ✧ 'pooldestroy' releases all pool memory to the system
- ✧ No need to call poolfree right before a pooldestroy
- ✧ Can make entire **traversals** dead (ADCE removes loop).
for (list *L = ..., L, L = L->Next) poolfree(PD, L);
pooldestroy(PD).

Pool Coalescing for Locality

- So far, we've assigned each node to a pool:
 - Keeps nodes homogenous
 - Better support for later analyses & transformations
- Real data structures have multiple pools:
 - Pool allocate subset? Make some share a pool?

Program pool properties

- Large programs have many pools
- # args added is very reasonable
- Most pools are type-safe

Program	LOC	Static Pools	Type Safe	Dyn. Pools	Num Args

Program pool properties

- Large programs have many pools
- # args added is very reasonable
- Most pools are type-safe

Biggest problem: Custom allocators

[illegible]

Pool alloc performance effect

- 2/3 programs: no substantial gain/loss

1 case: 9.4% gain

4 cases: ~20% gain

2 cases: 34/41% gain

1 case: 100% gain

- Unlike applications, benchmarks typically don't fragment heap!

Cache Miss Reduction

Miss rate measured with perfctr on 3Ghz Pentium 4 Xeon

Cache Miss Reduction

Miss rate measured with perfctr on 3Ghz Pentium 4 Xeon

Pool alloc performance effect

- 2/3 programs: no substantial gain/loss

1 case: 9.4% gain

4 cases: ~20% gain

2 cases: 34/41% gain

1 case: 100% gain

- Unlike applications, benchmarks typically don't fragment heap!

Pool Allocation Highlights

- **Transform data structures to use pool library**
- **Give compiler info & partial layout control**
- **Can dramatically improve DS locality:**
 - ◊ Defragment data structures
 - ◊ Often lays out nodes in allocation order
- **Opens the door for new applications!**
 - by combining static analysis with runtime control

Talk Outline

- Lifelong Program Analysis & Optimization
- LLVM as a Compiler Infrastructure
- Recursive DS Analysis / Transformations
- Virtual Instruction Set Computing
- Summary

VISC: Virtual Instruction Set Computers

Future VISC Research Goals

■ Processor and Micro-architecture Design

- ❖ New software-controlled micro-architectural mechanisms
- ❖ Explicitly parallel micro-architectures, visible only to translator
- ❖ Hardware fault tolerance through software translation

■ Compilers and Optimization

- ❖ High-level abstractions of parallelism in the V-ISA

Average for x86: About 2.6 Instructions per LLVA instruction

Average for Sparc: About 3.2 instructions per LLVA instruction

⇒ *Very small semantic gap ; clear performance relation*

Summary

■ LLVM Compiler Infrastructure

- ✧ Low-Level IR, High-Level capabilities
- ✧ Strong platform for supporting research
- ✧ Publicly available: <http://llvm.cs.uiuc.edu/>

■ Macroscopic Data Structure Techniques

- ✧ Analyze and transform entire data structures
- ✧ Works on real programs (hopefully soon MSIL too!)

■ VISC Processor Design

- ✧ Give architects ability to innovate with their ISA
- ✧ Many hard and interesting problems remain

Any (more) questions??
